

**Wood veneer** is a natural product, and its pattern, hue or tint might differ slightly, just like doors made of the same kind of wood do. Veneer is subject to darkening on exposure to light, which is a natural process, chiefly during the first eight or so weeks. This is especially noticeable with cherry veneer. It is advisable to move around objects sitting on shelves in order to ensure a more homogeneous hue owing to wood darkening, especially early on in the process. Uneven light absorption might result in permanent discoloration. Due to the same wood characteristic, it might take quite some time before its hue gets to harmonize with older objects made of the same material. Proper wood care requires soft and slightly damp dust cloth. Veneer must be prevented from long-term exposure to water, so a wet cloth should not be left lying on veneer. Wooden surfaces need to be protected from damage by means of special pads, preventing direct contact with materials that might be harmful from a chemical or mechanical point of view (e.g. coloring materials or sharp-edged objects).
